## Storing of slow light

$$| m{D} 
angle \sim | m{g} 
angle - rac{\Omega_{m{
ho}}}{\Omega_{m{c}}} | m{s} 
angle$$

- Information on probe beam is contained in the atomic coherence
- Storing of light—switching off control beam; information in the atomic coherence is retained
- Releasing—switch on control beam

## Storing of slow light

$$|D
angle \sim |g
angle - rac{\Omega_{
m 
ho}}{\Omega_{
m c}}|s
angle$$

- Information on probe beam is contained in the atomic coherence
- Storing of light—switching off control beam; information in the atomic coherence is retained
- Releasing—switch on control beam

Dark state

$$|D
angle \sim |g
angle - rac{\Omega_{
m 
ho}}{\Omega_{
m c}}|s
angle$$

- Information on probe beam is contained in the atomic coherence
- Storing of light—switching off control beam; information in the atomic coherence is retained

• Releasing—switch on control beam

$$|m{D}
angle \sim |m{g}
angle - rac{\Omega_{m{
ho}}}{\Omega_{m{c}}}|m{s}
angle$$

- Information on probe beam is contained in the atomic coherence
- Storing of light—switching off control beam; information in the atomic coherence is retained
- Releasing—switch on control beam

#### • Initial storage times (L. V. Hau et al, Nature 2001): 1 ms

## First try: double A scheme

Used for stationary light

< 47 ▶

 $\equiv \rightarrow$ 

## Double $\Lambda$ scheme: bad for our purposes

- Only one dark state can be formed
- Only one dark state polariton (propagating without absorbtion)
- For multicomponent slow light we need to add more levels.

#### • Only one dark state can be formed

- Only one dark state polariton (propagating without absorbtion)
- For multicomponent slow light we need to add more levels.

## Double tripod setup

æ

イロト イポト イヨト イヨ
#### Possible experimental realization

- Atoms like rubidium or sodium.
- Transitions between the magnetic states of two hyperfine levels with F = 1 and 2 for the ground and excited state manifolds.
- Both probe beams are circularly σ<sup>+</sup> polarized, all four control beams are circularly σ<sup>-</sup> polarized.

Julius Ruseckas (Lithuania)

Multi-component slow light

### Double tripod setup

 ${\cal E}_1$  and  ${\cal E}_2$  drive different atomic transitions which are interconnected if  $\langle B_1|B_2\rangle \neq 0$ 

< 同 ト < 三 ト < 三

## Double tripod setup

#### Limiting cases:

- $\langle B_1 | B_2 \rangle = 0$  two not connected tripods
- $\langle B_1 | B_2 \rangle = 1$  double Lambda setup
- $0 < |\langle B_1 | B_2 \rangle| < 1$  two connected tripods

## Propagation of slow light

$$(c^{-1}+\hat{v}^{-1})\frac{\partial}{\partial t}\mathcal{E}-\frac{\mathrm{i}}{2k}\nabla^{2}\mathcal{E}-\frac{\mathrm{i}}{2}k\mathcal{E}+\mathrm{i}\hat{v}^{-1}\hat{D}\mathcal{E}=0$$

$$\hat{D} = \hat{\Omega}\hat{\delta}\hat{\Omega}^{-1} - \mathrm{i}\hat{\Omega}\frac{\partial}{\partial t}\hat{\Omega}^{-1}$$

is a matrix due to two-photon detuning,

$$\hat{v}^{-1} = \frac{g^2 n}{c} (\hat{\Omega}^{\dagger})^{-1} \hat{\Omega}^{-1}$$

is a matrix of inverse group velocity (not necessarily diagonal).

Here

## Propagation of slow light

$$(c^{-1}+\hat{v}^{-1})\frac{\partial}{\partial t}\mathcal{E}-\frac{\mathrm{i}}{2k}\nabla^{2}\mathcal{E}-\frac{\mathrm{i}}{2}k\mathcal{E}+\mathrm{i}\hat{v}^{-1}\hat{D}\mathcal{E}=0$$

Here

$$\hat{D} = \hat{\Omega}\hat{\delta}\hat{\Omega}^{-1} - \mathrm{i}\hat{\Omega}\frac{\partial}{\partial t}\hat{\Omega}^{-1}$$

is a matrix due to two-photon detuning,

$$\hat{\boldsymbol{v}}^{-1} = \frac{g^2 n}{c} (\hat{\Omega}^{\dagger})^{-1} \hat{\Omega}^{-1}$$

is a matrix of inverse group velocity (not necessarily diagonal).

- Counter-propagating beams
- Non-zero two photon detuning  $\delta_1 = -\delta_2 \equiv \delta \neq 0$
- Dirac type equation with non-zero mass for two component slow light:

$$\mathrm{i}\frac{\partial}{\partial t}\tilde{\mathcal{E}} = -\mathrm{i}v_0\sigma_z\frac{\partial}{\partial z}\tilde{\mathcal{E}} + \delta\sigma_y\tilde{\mathcal{E}}$$

Here 
$$v_0 = rac{c\Omega^2}{g^2 r_0}$$

A gap in dispersion ("electron-positron" type spectrum)

- Counter-propagating beams
- Non-zero two photon detuning  $\delta_1 = -\delta_2 \equiv \delta \neq 0$
- Dirac type equation with non-zero mass for two component slow light:

$$\mathrm{i}\frac{\partial}{\partial t}\tilde{\mathcal{E}} = -\mathrm{i}v_0\sigma_z\frac{\partial}{\partial z}\tilde{\mathcal{E}} + \delta\sigma_y\tilde{\mathcal{E}}$$

Here 
$$v_0 = rac{c\Omega^2}{g^2 r_0}$$

A gap in dispersion ("electron-positron" type spectrum)

THE 1 A

- Counter-propagating beams
- Non-zero two photon detuning  $\delta_1 = -\delta_2 \equiv \delta \neq 0$
- Dirac type equation with non-zero mass for two component slow light:

$$\mathrm{i}\frac{\partial}{\partial t}\tilde{\mathcal{E}} = -\mathrm{i}v_0\sigma_z\frac{\partial}{\partial z}\tilde{\mathcal{E}} + \delta\sigma_y\tilde{\mathcal{E}}$$

Here 
$$v_0 = \frac{c\Omega^2}{g^2 n}$$

A gap in dispersion ("electron-positron" type spectrum)

- Counter-propagating beams
- Non-zero two photon detuning  $\delta_1 = -\delta_2 \equiv \delta \neq 0$
- Dirac type equation with non-zero mass for two component slow light:

$$\mathrm{i}\frac{\partial}{\partial t}\tilde{\mathcal{E}} = -\mathrm{i}v_0\sigma_z\frac{\partial}{\partial z}\tilde{\mathcal{E}} + \delta\sigma_y\tilde{\mathcal{E}}$$

Here 
$$v_0 = \frac{c\Omega^2}{g^2r}$$

A gap in dispersion ("electron-positron" type spectrum)

• Relativistic particle-antiparticle dispersion:

$$\Delta\omega^{\pm} = \pm \sqrt{v_0^2 \Delta k^2 + \delta^2}$$

•  $\hbar \delta = m v_0^2$  — gap width, *m* — polariton effective mass

• Relativistic particle-antiparticle dispersion:  $\Delta \omega^{\pm} = \pm \sqrt{v_0^2 \Delta k^2 + \delta^2}$ 

•  $\hbar \delta = m v_0^2$  — gap width, m — polariton effective mass

# How to create multi-component stationary light?

< <p>I > < </p>

#### Configuration with counter-propagating beams.

- Initially two-photon detuning  $\delta$  is zero
- and only one probe beam  $\mathcal{E}_1$  with central frequency  $\Delta \omega = 0$  is incident on the atomic cloud
- resulting in slow light, propagating with the velocity v<sub>0</sub>

- Configuration with counter-propagating beams.
- Initially two-photon detuning  $\delta$  is zero
- and only one probe beam  $\mathcal{E}_1$  with central frequency  $\Delta \omega = 0$  is incident on the atomic cloud
- resulting in slow light, propagating with the velocity v<sub>0</sub>

- Configuration with counter-propagating beams.
- Initially two-photon detuning  $\delta$  is zero
- and only one probe beam  $\mathcal{E}_1$  with central frequency  $\Delta \omega = 0$  is incident on the atomic cloud
- resulting in slow light, propagating with the velocity  $v_0$

- Configuration with counter-propagating beams.
- Initially two-photon detuning  $\delta$  is zero
- and only one probe beam  $\mathcal{E}_1$  with central frequency  $\Delta \omega = 0$  is incident on the atomic cloud
- resulting in slow light, propagating with the velocity v<sub>0</sub>

- When the wave packet of the beam  $\mathcal{E}_1$  is inside the cloud, the two-photon detuning is suddenly increased from 0 to  $\delta$
- A gap in the dispersion forms
- If the width in frequency space is smaller than the width of the gap  $2\delta$
- two-component stationary light is created

- two-component stationary light is created

モンマモ

- When the wave packet of the beam  $\mathcal{E}_1$  is inside the cloud, the two-photon detuning is suddenly increased from 0 to  $\delta$
- A gap in the dispersion forms
- If the width in frequency space is smaller than the width of the gap  $2\delta$
- two-component stationary light is created

Light is converted to superposition of eigenstates with positive and negative frequencies.

Instead of propagating, light oscillates between two probe fields:

$$\left(\begin{array}{c} \mathcal{E}_1\\ \mathcal{E}_2 \end{array}\right) = \left(\begin{array}{c} \cos(\delta t)\\ \sin(\delta t) \end{array}\right)$$

 At later time t = t<sub>r</sub>, decreasing the two-photon detuning δ back to zero, the stationary light is converted back to slow light

Probe beam can be frozen in the medium forming a two-component stationary light and subsequently released.

Instead of propagating, light oscillates between two probe fields:

$$\left(\begin{array}{c} \mathcal{E}_1\\ \mathcal{E}_2 \end{array}\right) = \left(\begin{array}{c} \cos(\delta t)\\ \sin(\delta t) \end{array}\right)$$

## Limiting factors

Spreading of the wave packet due to parabolic dispersion. Time to double the width

$$t_{\rm d} = \frac{\sqrt{3\delta}}{2\sigma_\omega^2}$$

• Diffusion due to non-adiabatic terms. Diffusion coefficient is  $L_{abs}v_0$ . Time to double the width

$$t_{\rm d} = \frac{3v_0}{4L_{\rm abs}\sigma_\omega^2}$$

• Decay of stationary light due to non-adiabatic terms. The effective decay rate of the probe light fields

 Decay of stationary light due to non-adiabatic terms. The effective decay rate of the probe light fields

$$\tau^{-1} = \gamma \frac{\delta^2}{\Omega^2}$$

- Under certain conditions the slow light can be described by a relativistic equation of the Dirac-type for a particle of a finite mass, dispersion branches are separated by an energy gap.
- The propagation of the probe beam can then be controlled by changing the relative phase of the control beams or introducing a two-photon detuning.
- Using these means the probe beams can be frozen in the medium forming a two-component stationary light and subsequently released.
