

# Continuous transition from the extensive to the non-extensive statistics in a simple model

Julius Ruseckas    Aleksejus Kononovičius

Institute of Theoretical Physics and Astronomy, Vilnius University, Lithuania

September 10, 2014

# Outline

Motivation

Proposed model

Mesoscopic description

New network formation model

Properties of the model

Summary

# Motivation

- ▶ Systems with **long-range** interactions:
  - ▶ gravitational forces
  - ▶ Coulomb forces in globally charged systems
  - ▶ vortices in two-dimensional fluid mechanics
  - ▶ trapped charged particles
- ▶ **Violate** extensivity and additivity, basic properties used to derive the thermodynamics of a system

# Systems with long-range interactions

Exhibit **unusual** behavior:

- ▶ inequivalence of the microcanonical and canonical ensembles
- ▶ negative microcanonical specific heat
- ▶ slow relaxation
- ▶ broken ergodicity
- ▶ long-lived non-equilibrium quasistationary states (QSS)
- ▶ violent relaxation into these states
- ▶ non-Gaussian distributions
- ▶ non-exponential relaxations for autocorrelations

# Non-extensive statistical mechanics

- ▶ Intended to describe some of the systems with long-range interactions by generalizing the Boltzmann-Gibbs statistics
- ▶ Based on a generalized **entropy**

$$S_q = \frac{1 - \int [\rho(x)]^q dx}{q - 1}$$

# Non-extensive statistical mechanics

Maximization of  $q$ -entropy with appropriate constraints leads to a  $q$ -Gaussian distribution

$$p(x) = C_q \exp_q(-A_q x^2)$$

Here

$$\exp_q(x) \equiv [1 + (1 - q)x]_+^{\frac{1}{1-q}}$$

is the  $q$ -exponential function

# Systems with long-range interactions

- ▶ Mathematical description is usually **complicated**.
- ▶ Simple models providing some degree of intuition about non-extensive statistical mechanics can be useful for understanding it

## Goal

To construct a **simple** model with long-range interactions.

# Proposed model

- ▶  $N$  particles of spin- $\frac{1}{2}$
- ▶ Each particle interacts with some number of other particles
- ▶ Dynamics is described as a Markov process in a continuous time
- ▶ The transition rate for a particle  $i$  having the spin  $X$  to flip it's spin is

$$p_i(X \rightarrow Y) = \sigma + hn_i(Y)$$

Here  $n_i(Y)$  is the number of particles it interacts with, having the opposite spin  $Y$

# Mean-field approximation

Mean transition rate

$$\langle p_i(X \rightarrow Y) \rangle = \sigma + h \langle d \rangle \frac{N_Y}{N}$$

Here  $N_Y$  is the total number of particles with spin  $Y$  and  $\langle d \rangle$  is the average number of particles interacting with a given particle.

Transition rates of one-step stochastic process:

$$p(n \rightarrow n + 1) = (N - n) \eta_1(n, N)$$

$$p(n \rightarrow n - 1) = n \eta_2(n, N)$$

where  $n$  is the number of particles with the spin pointing up and

$$\eta_1 = \langle p_i(\downarrow \rightarrow \uparrow) \rangle \quad \eta_2 = \langle p_i(\uparrow \rightarrow \downarrow) \rangle$$

represent per-particle transition rates

# Mean-field approximation

Transition rates:

$$\eta_1 = \sigma + \frac{h'}{N}n$$

$$\eta_2 = \sigma + \frac{h'}{N}(N - n)$$

The term with  $h' = h\langle d \rangle$  represents interactions between particles

## Mesoscopic description of the model

Fokker-Planck equation in the limit of large  $N$ :

$$\begin{aligned} \frac{\partial}{\partial t} P_x(x, t) = & \frac{\partial}{\partial x} [x\eta_2 - (1-x)\eta_1] P_x(x, t) \\ & + \frac{1}{2N} \frac{\partial^2}{\partial x^2} [(1-x)\eta_1 + x\eta_2] P_x(x, t) \end{aligned}$$

Here  $x = \frac{n}{N}$

# Short-range interactions

- ▶ Transition rates  $\eta_1$  and  $\eta_2$  depend only on  $x = n/N$
- ▶ In the thermodynamic limit  $N \rightarrow \infty$ , the diffusion term becomes negligible
- ▶ Detailed balance:

$$x_0 \eta_2(x_0) = (1 - x_0) \eta_1(x_0).$$

- ▶ Gaussian distribution

$$\sqrt{\frac{NA}{\pi}} \exp \left[ -NA(x - x_0)^2 \right]$$

- ▶ The width is proportional to  $1/\sqrt{N}$

## Conclusion

To represent long-range interactions, the transition rates  $\eta_1$  and  $\eta_2$  should explicitly **depend on  $N$** .

# Proposed model

We assume that

$$\langle d \rangle \sim N^\alpha$$

with  $0 \leq \alpha \leq 1$

# Network of interactions

Interaction between particles can be represented by a network.

$\langle d \rangle$  is the mean degree, it should scale with the number of nodes as  $N^\alpha$

Known networks, important in social systems:

- ▶ Random network,  $\langle d \rangle \sim N$
- ▶ Scale-free network,  $\langle d \rangle \sim \text{const}$

## Conclusion

We need a network **intermediate** between a random network and a scale-free network

# New network formation model

1. Add a new node to the network
2. Connect the new node to another node with the probability proportional to its degree.
3. Add additional connections to the immediate neighbours of the node in the step 2 with the probability

$$p = p_0 d^{-\gamma},$$

where  $d$  is a degree of the node in the step 2.

# New network formation model

(a)

$$\gamma = 0$$

(e)

$$\gamma = 1$$

$$\gamma = 0.3$$

(c)

## Scaling of the mean degree

$$\langle d \rangle \sim N^\alpha \quad \alpha \approx (1 - \gamma)^2$$

# Steady state

Steady state distribution is a  $q$ -Gaussian

$$P_0(x) = C' \exp_q \left[ -A_q \left( x - \frac{1}{2} \right)^2 \right]$$

with

$$q = 1 - \frac{1}{\varepsilon N^{1-\alpha} - 1}, \quad A_q = 2N^{1-\alpha} \frac{1 - \frac{1}{\varepsilon} N^{\alpha-1}}{\frac{1}{2\varepsilon} + N^{-\alpha}}$$

Here

$$\varepsilon = \frac{\sigma}{d_0 h}$$

with  $d = d_0 N^\alpha$

# Steady state

Steady state distribution for different values of  $\alpha$

Steady state distribution for different values of  $N$

## Steady state: long-range interactions

If the interactions are long-range,  $\alpha = 1$ , the steady state distribution in the limit  $N \rightarrow \infty$  does not depend on  $N$

$$P_0(x) \sim [x(1-x)]^{\varepsilon-1}$$

Non-extensivity parameter

$$q = 1 - \frac{1}{\varepsilon - 1}$$

## Steady state: $\alpha < 1$

When  $\alpha < 1$ , in the limit of large  $N$  the steady state distribution is approximately Gaussian

$$P_0(x) \sim \exp \left[ -N^{1-\alpha} A \left( x - \frac{1}{2} \right)^2 \right]$$

with

$$A = \begin{cases} \frac{2}{\frac{1}{2\varepsilon} + 1}, & \alpha = 0 \\ 4\varepsilon, & 0 < \alpha < 1 \end{cases}$$

When  $\alpha > 0$ , the fluctuations decay not as  $1/\sqrt{N}$  but as  $1/\sqrt{N^{\alpha-1}}$

# Fluctuation in time

Langevin equation corresponding to the Fokker-Planck equation:

$$dx = \sigma(1 - 2x)dt + \sqrt{\frac{1}{N}(2h\langle d \rangle x(1 - x) + \sigma)}dW_t$$

- ▶ When  $\alpha < 1$ , in the limit of  $N \rightarrow \infty$ , macroscopic fluctuations of  $x$  vanish
- ▶ When  $\alpha = 1$ , the fluctuations of the ratio  $N_{\downarrow}/N_{\uparrow}$  have  $1/f^{\beta}$  power spectral density in a wide region of frequencies, growing with  $N$

# 1/f noise

We have  $1/f$  noise when  $\frac{\sigma}{d_0 h} = 2$

$q > 1$ ?

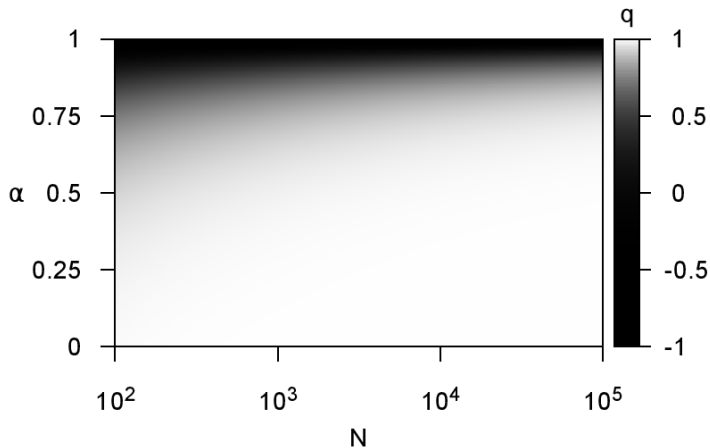

It can be shown that  $q > 1$  only when  $h < 0$   
However, this leads either to

1.  $q \rightarrow 1$  as  $N \rightarrow \infty$
2. Model is valid only when

$$N < \frac{2 - q}{q - 1}$$

# Transition from extensive to non-extensive statistics

# Summary

- ▶ The steady state distribution for a finite system size is described by  $q$ -Gaussian
- ▶ This confirms the similarity of small systems to large systems with truly long-range interactions
- ▶ The extensive behaviour increases with increase of  $N$
- ▶ For  $\alpha = 1$  the model is non-extensive for all  $N$
- ▶ The fluctuations decay more slowly with increasing  $N$  for larger values of  $\alpha$
- ▶ Proposed model cannot give  $q > 1$  for large  $N$

Thank you for your  
attention!
