  - Rashba-type Hamiltionian with spin 1

- Degenerate Fermi gas \Leftarrow Electrons in solids
- Atoms in optical lattices

#### Advantages and disadvantages of cold atoms

- Advantage: Freedom in changing experimental parameters that are often inaccessible in standard solid state physics
- **Disadvantage:** Trapped atoms are electrically neutral particles. Direct analogy with magnetic properties of solids is not necessarily straightforward

- Degenerate Fermi gas  $\iff$  Electrons in solids
- Atoms in optical lattices

### Advantages and disadvantages of cold atoms

- Advantage: Freedom in changing experimental parameters that are often inaccessible in standard solid state physics
- **Disadvantage:** Trapped atoms are electrically neutral particles. Direct analogy with magnetic properties of solids is not necessarily straightforward

Cold atomic gases are an analog not only to the solid state physics. Creation of the effective gauge potentials allows for the motion of cold atoms to be described by equations that usually appear in the elementary particle physics.

- Non-Abelian gauge potentials
- Magnetic monopole
- Ultrarelativistic Dirac fermions
- Zitterbewegung
- Negative reflection

• Coriolis force:

$$\mathbf{F}_{C} = 2m\mathbf{v} \times \Omega$$

• Lorenz force:

 $\mathbf{F}_L = q \, \mathbf{v} imes \mathbf{B}$ 

Rotation is similar to the magnetic field.

#### • Rotation — usual method to create effective magnetic field

- Constant effective magnetic field  $B_{\rm eff} \sim \Omega$
- Trapping frequency  $\omega_{\rm eff} = \omega \Omega$
- Effective magnetic field acts on atoms in the same way
- Optical lattices having asymmetry in the atomic transitions between the lattice sites.
  - Abelian effective gauge potentials

# Adiabatic Approximation

Substituting into the Schrödinger equation  $i\hbar\partial/\partial t|\Phi\rangle = \hat{H}|\Phi\rangle$  one can write the equation for the coefficients  $\Psi_n(\mathbf{r}, t)$  in the form

$$i\hbar \frac{\partial}{\partial t} \Psi = \left[ \frac{1}{2M} (-i\hbar \nabla - \mathbf{A})^2 + V + \beta \right] \Psi_{\pm}$$

where

$$\Psi = \begin{pmatrix} \Psi_{1} \\ \cdots \\ \Psi_{n} \end{pmatrix},$$
  
$$\mathbf{A}_{n,n'} = i\hbar \langle \chi_{n}(\mathbf{r}, t) | \nabla \chi_{n'}(\mathbf{r}, t) \rangle,$$
  
$$V_{n,n'} = \varepsilon(\mathbf{r}, t) \delta_{n,n'} + \langle \chi_{n}(\mathbf{r}, t) | \hat{V}(\mathbf{r}) | \chi_{n'}(\mathbf{r}, t) \rangle,$$
  
$$\beta_{n,n'} = -i\hbar \langle \chi_{n}(\mathbf{r}, t) | \frac{\partial}{\partial t} \chi_{n'}(\mathbf{r}, t) \rangle.$$

4 A N

### Non-degenerate states

The first state is well separated from the rest. Off-diagonal terms are neglected.

$$i\hbar \frac{\partial}{\partial t}\Psi_1 = \left[\frac{1}{2M}(-i\hbar \nabla - \mathbf{A})^2 + V + \phi + \beta\right]\Psi_1,$$

where

$$\begin{aligned} \mathbf{A} &= \mathbf{A}_{1,1}, \\ V &= V_{1,1}, \\ \phi &= \frac{1}{2M} \sum_{n \neq 1} \mathbf{A}_{1,n} \cdot \mathbf{A}_{n,1}. \end{aligned}$$

A (10) > A (10) > A (10)

The first q dressed states are degenerate and these levels are well separated from the remaining N - q

$$i\hbar\frac{\partial}{\partial t}\tilde{\Psi} = \left[\frac{1}{2M}(-i\hbar\nabla - \mathbf{A})^2 + \mathbf{V} + \phi + \beta\right]\tilde{\Psi},$$

where **A** and  $\phi$  are truncated  $q \times q$  matrices,

$$\phi_{n,n'} = \frac{1}{2M} \sum_{m=q+1}^{N} \mathbf{A}_{n,m} \cdot \mathbf{A}_{m,n'}.$$

The effective vector potential **A** is called the Mead-Berry connection. The effective scalar potential  $\phi$  is called the Born-Huang potential.

Gauge potentials for cold atoms

August 30, 2010 37/41

Spin-1 Rashba-type Hamiltonian

$$\hat{H} = \frac{1}{2m}(\hat{\mathbf{p}} + \hbar\kappa \mathbf{J}_{\perp})^2 + V$$

where  $\mathbf{J}_{\perp}$  is the projection of spin-1 operator onto the *xy* plane.

Spin-1 Rashba-type Hamiltonian

$$\hat{H} = \frac{1}{2m}(\hat{\mathbf{p}} + \hbar\kappa \mathbf{J}_{\perp})^2 + V$$

where  $\mathbf{J}_{\perp}$  is the projection of spin-1 operator onto the *xy* plane.

# Comparison of transmission probabilities for spin-1/2 and spin-1 systems

- Light beams with relative orbital angular momentum can introduce Abelian and non-Abelian effective gauge potentials acting on the electrically neutral atoms.
- Non-Abelian fields can be formed for cold atoms using the plane-wave setups. This was not possible for the Abelian fields.
- Atomic motion in non-Abelian fields exhibits a number of non-trivial features, such as their quasirelativistic behavior or the negative refraction and reflection.
- The plane wave setups can lead to the spin 1/2 or the spin 1 Rashba-type Hamiltonian for cold atoms.

4 3 > 4 3
