## ABSTRACT

We study laser induced spin-orbit (SO) coupling in cold atom systems where lasers couple three internal states to a pair of excited states, in a double tripod topology. Proper choice of laser amplitudes and phases produces a Hamiltonian with a doubly degenerate ground state separated from the remaining “excited” eigenstates by gaps determined by the Rabi frequencies of the atom-light coupling. After eliminating the excited states with a Born-Oppenheimer approximation, the Hamiltonian of the remaining two states includes Dresselhaus (or equivalently Rashba) SO coupling. Unlike earlier proposals, here the SO coupled states are the two lowest energy “dressed” spin states and are thus immune to collisional relaxation. Finally, we discuss a specific implementation of our system using Raman transitions between different hyperfine states within the electronic ground state manifold of nuclear spin  $I = 3/2$  alkali atoms.

**Keywords:** Ultracold atoms, light-induced gauge potentials, Rashba-Dresselhaus spin-orbit coupling

## 1. INTRODUCTION

Spin-orbit (SO) coupling of the Rashba<sup>1-3</sup> or Dresselhaus<sup>4,5</sup> type has been widely studied in condensed matter physics. Such SO coupling – linear in momentum – is equivalent to non-abelian vector potentials built from the spin-1/2 Pauli matrices.<sup>6</sup> Laser-atom coupling in the tripod configuration<sup>7-9</sup> gives rise to two degenerate dark states whose Hamiltonian is equivalent to that of spin 1/2-particles with Rashba-Dresselhaus (RD) SO coupling.<sup>10-15</sup> With such coupling, the atomic dark states play the role of the spin-up and spin-down states. In the tripod scheme, the degenerate dark states are not the lowest energy eigenstates of the atom-light Hamiltonian, thus atoms can decay out of the dark state manifold due to collisions and other relaxation processes, potentially impairing experimental realizations.

Here, we propose a technique for generating RD type SO coupling using five laser-dressed levels of an atom. Lasers couple each of three internal atomic states to two other mutually uncoupled states to form a double tripod (Fig. 1). We show that with proper choice of the amplitudes and phases of the laser fields the atom-light Hamiltonian has a pair of degenerate eigenstates with the lowest energy. These are separated from the remaining eigenstates by a gap determined by the Rabi frequencies of the atom-light coupling. As in the tripod case, elimination of the excited states produces an effective Hamiltonian containing RD type SO coupling for the resulting spin-1/2 system. Since the degenerate states are lowest in energy, they do not experience relaxation to other states. (Spontaneous emission from the laser fields remains an issue.<sup>16</sup>)

## 2. FORMULATION

We consider atoms illuminated by several lasers that couple each of three internal atomic states  $|1\rangle$ ,  $|2\rangle$ ,  $|3\rangle$  with two others  $|e_1\rangle$ ,  $|e_2\rangle$  to form the double tripod setup depicted in Fig. 1. (Below, we show that the states  $|1\rangle$ ,  $|2\rangle$ ,  $|3\rangle$ ,  $|e_1\rangle$  and  $|e_2\rangle$  can all belong to a ground state manifold coupled with two photon Raman transitions.) Adopting the interaction representation and the rotating wave approximation, the atom light Hamiltonian is

$$\hat{H}_0 = -\hbar \sum_{p=1}^2 [(\Omega_{1,p}|e_p\rangle\langle 1| + \Omega_{2,p}|e_p\rangle\langle 2| + \Omega_{3,p}|e_p\rangle\langle 3|) + \text{H.c.}] . \quad (1)$$

Figure 1. A five level model atom interacting with a six lasers illustrating the double tripod coupling scheme.

$\Omega_{j,p}$  are the Rabi frequencies describing the coupling between the internal atomic states  $|j\rangle$  and  $|e_p\rangle$ .

It is convenient to introduce a pair of coupled (bright) states

$$|B_p\rangle = \frac{1}{\Omega_p} \sum_{j=1}^3 \Omega_{j,p}^* |j\rangle, \quad p = 1, 2, \quad (2)$$

where

$$\Omega_p^2 = \sum_{j=1}^3 |\Omega_{j,p}|^2 \quad (3)$$

are the total Rabi frequencies, with  $p = 1, 2$ . In terms of these new states, the Hamiltonian is

$$\hat{H}_0 = -\hbar \sum_{p=1}^2 \Omega_p |e_p\rangle \langle B_p| + \text{H.c.} \quad (4)$$

Thus, the total Rabi frequencies  $\Omega_p$  characterize the coupling strength between the atomic states  $|e_p\rangle$  and  $|B_p\rangle$ .

We consider the case where the states  $|B_1\rangle$  and  $|B_2\rangle$  are orthogonal,  $\langle B_2|B_1\rangle = 0$ , so that

$$\sum_{j=1}^3 \Omega_{j,2} \Omega_{j,1}^* = 0. \quad (5)$$

For the physical system illuminated by nearly uniform lasers of equal intensity, the Rabi frequencies  $\Omega_{j,p}$  are plane-waves with the same amplitude  $\Omega$  and the wave-vectors  $\mathbf{k}_j$ :

$$\Omega_{j,p} = \Omega e^{i\mathbf{k}_j \cdot \mathbf{r} + iS_{j,p}}, \quad \text{and} \quad S_{j,p} = (-1)^p \frac{\pi}{3} (j-2). \quad (6)$$

The choice of the phases  $S_{j,p}$  ensures the condition (Eq. 5) for the Rabi frequencies  $\Omega_{j,p}$ . In this case, the coupled states  $|B_p\rangle$  are

$$|B_p\rangle = \frac{1}{\sqrt{3}} \sum_{j=1}^3 e^{-i\mathbf{k}_j \cdot \mathbf{r} - iS_{j,p}} |j\rangle. \quad (7)$$

Note that by taking equal amplitudes of the Rabi frequencies  $\Omega_{j,p}$ , one arrives at equal coupling strengths between the states featured in the atomic Hamiltonian (Eq. 4):  $\Omega_1 = \Omega_2 = \sqrt{3}\Omega$ . As we shall see, this leads to degenerate pair of laser-dressed atomic ground states.

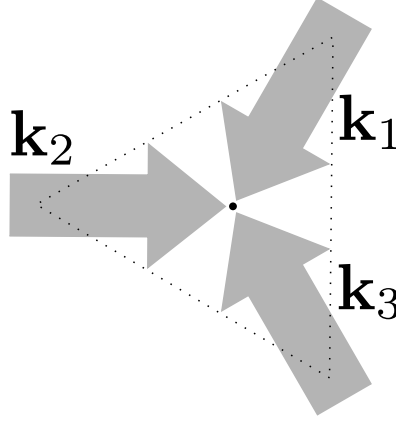

Figure 2. Geometry of coupling fields with wave-vectors forming an equilateral triangle

The Hamiltonian (Eq. 4) has eigenstates

$$|p, \pm\rangle = \frac{1}{\sqrt{2}}(|B_p\rangle \pm |e_p\rangle) \quad (8)$$

with eigenenergies

$$\varepsilon_{\pm} = \mp \hbar \sqrt{3} \Omega. \quad (9)$$

Additionally, there is an uncoupled (dark) state  $|D\rangle$ , which is orthogonal to both  $|B_1\rangle$  and  $|B_2\rangle$  and has a zero energy:  $\varepsilon_D = 0$ . The dark state can be found from the conditions  $\langle D|B_1\rangle = 0$ ,  $\langle D|B_2\rangle = 0$  together with Eq. (7), giving:

$$|D\rangle = \frac{1}{\sqrt{3}} \sum_{j=1}^3 e^{-i\mathbf{k}_j \cdot \mathbf{r}} |j\rangle. \quad (10)$$

The states  $|1, +\rangle$  and  $|2, +\rangle$  represent a pair of degenerate ground states with energy  $\varepsilon_+ = -\hbar \sqrt{3} \Omega$ . The remaining eigenstates  $|D\rangle$ ,  $|1, -\rangle$ , and  $|2, -\rangle$  are separated from the ground states by energies  $\hbar \sqrt{3} \Omega$  and  $2\hbar \sqrt{3} \Omega$ , respectively.

### 3. GENERATION OF THE RASHBA-DRESSELHAUS COUPLING

#### 3.1 Adiabatic approximation: reduction to spin-1/2

Below, we apply the adiabatic approximation by assuming that the atoms evolve within their internal ground state manifold. This Born-Oppenheimer approximation is legitimate when the Rabi frequency  $\Omega$  significantly exceeds the atoms kinetic energy. The atom is then characterized by a two-component wave-function

$$\Psi(x) = \begin{pmatrix} \Psi_1(x) \\ \Psi_2(x) \end{pmatrix}, \quad (11)$$

where  $\Psi_1(x)$  and  $\Psi_2(x)$  are the wave-functions of the dressed ground states  $|1, +\rangle$  and  $|2, +\rangle$ , respectively.

The spinor wave-function  $\Psi$  obeys the Schrödinger equation  $i\hbar \partial / \partial \Psi = H \Psi$  with the Hamiltonian:

$$H = \frac{1}{2m} (\mathbf{p} - \mathbf{A})^2 + \Phi + V, \quad (12)$$

where  $m$  is the atomic mass and  $V$  is the external potential. Here also  $\mathbf{A}$  and  $\Phi$  are the geometric vector and scalar potentials appearing due to the position dependence of the atomic internal states  $|1, +, \mathbf{r}\rangle$  and  $|2, +, \mathbf{r}\rangle$ .

Such geometric potentials emerge in many areas of physics.<sup>17-22</sup> In the present situation, the geometric potentials are  $2 \times 2$  matrices with the elements:

$$\mathbf{A}_{s,q} = i\hbar \langle s, +, \mathbf{r} | \nabla | q, +, \mathbf{r} \rangle, \quad \Phi_{s,q} = -\frac{\hbar^2}{2m} \sum_{X,\mathbf{r}} \langle s, +, \mathbf{r} | \nabla | X, \mathbf{r} \rangle \langle X, \mathbf{r} | \nabla | q, +, \mathbf{r} \rangle. \quad (13)$$

$|X, \mathbf{r}\rangle$  stands for the higher energy excluded states  $|1, -, \mathbf{r}\rangle$ ,  $|2, -, \mathbf{r}\rangle$  and  $|D, \mathbf{r}\rangle$ .

### 3.2 Vector and scalar potentials

Using Eqs. (7) and (8), the vector potential is

$$\mathbf{A}_{s,q} = \frac{\hbar}{6} \sum_{j=1}^3 \mathbf{k}_j e^{i\frac{2\pi}{3}(j-2)(s-q)}, \quad (14)$$

where  $s, q = 1, 2$ . We are interested in a situation where the wave-vectors form a triangle  $\mathbf{k}_1 + \mathbf{k}_2 + \mathbf{k}_3 = 0$ , so the diagonal elements of the vector potential are zero:  $\mathbf{A}_{s,s} = 0$ . In particular, we focus on the case where the wave vectors  $\mathbf{k}_j$  form a regular triangular shown in Fig. 2:

$$\mathbf{k}_j = \kappa \left\{ \mathbf{e}_x \cos \left[ \frac{2\pi}{3}(j-2) \right] + \mathbf{e}_y \sin \left[ \frac{2\pi}{3}(j-2) \right] \right\}. \quad (15)$$

In such a configuration, the vector potential is proportional to the projection of the spin 1/2 operator along the  $x$ - $y$  plane:

$$\mathbf{A} = \frac{\hbar\kappa}{4} \check{\boldsymbol{\sigma}}_{\perp}, \quad \check{\boldsymbol{\sigma}}_{\perp} = \check{\sigma}_x \mathbf{e}_x + \check{\sigma}_y \mathbf{e}_y, \quad (16)$$

where  $\check{\sigma}_x$  and  $\check{\sigma}_y$  are the Pauli matrices, and  $\mathbf{e}_x$  and  $\mathbf{e}_y$  are the unit Cartesian vectors. Thus the ground-state atoms experience SO coupling of the Dresselhaus type, equivalent to a non-abelian vector potential proportional to the spin operator  $\check{\boldsymbol{\sigma}}_{\perp}$ . Such SO coupling can equivalently be recast in the Rashba form, by relabeling the coordinate axis  $\mathbf{e}_x \rightarrow \mathbf{e}_y$  and  $\mathbf{e}_y \rightarrow \mathbf{e}_x$ .

Lastly, for the wave-vectors given by Eq. (15) the scalar potential is

$$\Phi = \frac{3}{8} \frac{\hbar^2 \kappa^2}{M} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}. \quad (17)$$

Thus the scalar potential is proportional to the unit matrix and provides a constant energy offset.

### 3.3 Implementation of the scheme

We now discuss a possible experimental implementation of the double tripod scheme applicable to the commonly used alkali-metal atoms. In order to avoid a rampant heating due to spontaneous emission, one can take the states  $|e_1\rangle$  and  $|e_2\rangle$  to be the hyperfine ground states with  $F = 1$  and  $F = 2$ , such as  $|e_1\rangle = |F = 1, m_F = 0\rangle$  and  $|e_2\rangle = |F = 2, m_F = 0\rangle$ , see Fig. 3. The states  $|j\rangle$  (with  $j = 1, 2, 3$ ) are different Zeeman sublevels of the ground state with total angular momentum  $F = 1$  or  $F = 2$ , such as  $|1\rangle = |F = 1, m_F = -1\rangle$ ,  $|2\rangle = |F = 1, m_F = 1\rangle$  and  $|3\rangle = |F = 2, m_F = -1\rangle$ . The coupling between the state  $|e_p\rangle$  and the state  $|j\rangle$  is provided by a pair of laser beams that induce a Raman transition under the condition of the two-photon resonance. The use of Raman transitions in this context is an extension to the double tripod case of a recent proposal<sup>23</sup> to implement a  $\Lambda$  (ladder) type scheme for the generation of an effective magnetic field by means of counter propagating laser beams.<sup>24, 25</sup>

Figure 3. Proposed experimental implementation of the double tripod scheme within the ground state manifolds of nuclear spin  $I = 3/2$  alkali atoms (with total angular momentum  $F = 1$  and  $F = 2$  hyperfine manifolds) such as rubidium or sodium. The lines and arcs with arrows indicate Raman transitions between different magnetic sublevels within the  $F = 1$  and  $F = 2$  hyperfine manifolds. The grey lines indicate atomic states which are not involved in the proposed coupling scheme.

#### 4. CONCLUDING REMARKS

We studied dressed Hamiltonian of Raman-driven cold atoms in which the lasers couple three atomic internal states to another two states in a double tripod topology. By properly choosing the amplitudes and phases of the laser fields the atom-light Hamiltonian has a pair of degenerate eigenstates with the lowest energy. They are separated from the remaining eigenstates by a gap determined by the Rabi frequencies of the atom-light coupling. Adiabatically eliminating the upper states, the atomic center of mass motion in the pair of the degenerate internal states is characterized by the SO coupling of the Rashba or Dresselhaus type for a spin 1/2 particle. Since the degenerate atomic states are the internal states with the lowest energy, there is no relaxation to other atomic states. This by-passes the problem arising in the previously studied tripod scheme<sup>9-15</sup> (or a more general  $N$ -pod scheme<sup>26</sup>) where the degenerate dark states represent the excited atomic internal states. Note that alternatively one can generate the SO coupling for a pair of lowest energy atomic states using a closed loop setup considered elsewhere.<sup>27</sup>

The suggested scheme can be implemented using the Raman transitions between the atomic hyperfine ground states. The creation of SO coupling for cold atoms has a number potential applications including *inter alia* their quasi-relativistic behavior and Zitterbewegung,<sup>13,28-30</sup> as well as generating SO coupled Bose-Einstein condensates or degenerate Fermi gases with unusual properties.<sup>15,31-33</sup>
